Windows PowerShell is a command-line shell and scripting language that helps IT professionals achieve greater control and productivity. Using a new, admin-focused scripting language, more than 230 standard command-line tools, and consistent syntax and utilities, Windows PowerShell allows IT professionals to more easily control system administration and accelerate automation.
Introduction

Estimated time to complete this lab
30 minutes

Objectives
In this lab, you will learn the fundamentals of using Windows PowerShell commands, known as cmdlets, including the following techniques:

- Exploring Windows PowerShell Help
  Windows PowerShell has a powerful documentation mechanism. Administrators can query the help subsystem with a unified command set. Developers are provided with a set of common tools to lower the time invested in documentation.

- Constructing a pipeline
  Windows PowerShell is different from other shells because it does not use strings as parameters; instead it uses .NET objects which can be navigated, processed, reflected, and formatted.

- Using formatting commands
  Windows PowerShell does not limit the kind of formatting that can be applied to a simple object nor does it place any restrictions on the destination of the output. Developers can extend the wide range of available choices through the development of cmdlets.

- Using filtering and sorting commands
  As a complement to formatting, filtering and sorting commands are very useful for cmdlet output manipulation. Windows PowerShell provides typical filtering and sorting cmdlets for most tasks, and developers can also extend them by creating new cmdlets.

- Using -WhatIf and -Confirm
  These are common switches you can apply to cmdlets.

- Working with variables
  Like any Windows-based scripting language, Windows PowerShell has variables too, but they are much more powerful than the variables in older scripting languages. Windows PowerShell variables are actually mapped to underlying classes in the Microsoft® .NET Framework. And in the Framework, variables are objects, meaning they can store data and also manipulate it in many ways.

- Working with providers
  The provider represents a set of stored data (e.g. the Microsoft Windows Registry, the Windows file system, Active Directory) that can be accessed and navigated through Windows PowerShell commands.
Prerequisites
Before working on this lab, you must have:

1. An understanding of concepts such as virtual machines, virtual hard disks, and virtual networks.
2. The ability to work in a command-line environment.

Overview of the lab
Windows PowerShell is a command-line shell and scripting language that helps IT professionals achieve greater control and productivity. Using a new admin-focused scripting language, more than 230 standard command-line tools, and consistent syntax and utilities, Windows PowerShell allows IT professionals to more easily control system administration and accelerate automation.

Intended audience
This lab is intended for network administrators who wish to learn the Windows PowerShell interface and language.

Virtual machine technology
This lab is completed using virtual machines that run on Windows Server 2012 Hyper-V technology. To log on to the virtual machines, press CTRL+ALT+END and enter the following credentials:

- Username: Administrator
- Password: Passw0rd!

Computers in this lab
This lab uses computers as described in the following table. Before you begin the lab, you must ensure that the virtual machines are started and then log on to the computers.

<table>
<thead>
<tr>
<th>Computer</th>
<th>Role</th>
<th>Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>DC</td>
<td>Domain controller</td>
<td>Domain controller</td>
</tr>
</tbody>
</table>

Note regarding pre-release software
Portions of this lab include software that is not yet released, and as such may still contain active or known issues. While every effort has been made to ensure this lab functions as written, unknown or unanticipated results may be encountered as a result of using pre-release software.

Note regarding user account control
Some steps in this lab may be subject to user account control. User account control is a technology which provides additional security to computers by requesting that users confirm actions that require administrative rights. Tasks that generate a user account control confirmation are denoted using a shield icon. If you encounter a shield icon, confirm your action by selecting the appropriate button in the dialog box that is presented.

Note on activation
The virtual machines for these labs may have been built by using software that has not been activated. This is by design in the lab to prevent the redistribution of activated software. The unactivated state of
software has been taken into account in the design of the lab. Consequently, the lab is in no way affected by this state. For operating systems other than Windows 8, please press Cancel or Close if prompted by an activation dialog box. If you are prompted by an Activate screen for Windows 8, press the Windows key to display the Start screen.
Exercise 1: Exploring Windows PowerShell

In this exercise, you will explore several Windows PowerShell commands and features including help, object formatting, and safety features.

diamond Perform all the exercises on DC.
arrow Every command has three different levels of help available:

1. The default view shows the command description and syntax.
2. The detailed view adds usage examples and complete documentation.
3. The full view adds command’s technical details including parameter and return value data types.

Reviewing the help available in Windows PowerShell

In this step, you will learn how to view the different levels of help content available for a cmdlet.

1. To open a new Windows PowerShell command window, on the taskbar, click Windows PowerShell.
2. At the Windows PowerShell command prompt, type the following command, and then press ENTER to see a list of available help topics.
   `help *`
3. The command will fill an entire screen and then pause. Press ENTER to show the next output line, or press SPACE BAR to advance to the next page.
Figure 1: Executing the Help command

In the output you can see a second column with a value of Alias, Cmdlet, Provider, or HelpFile. An alias is an alternative name for a command, usually an abbreviation or a name used by other shells for similar functionality. Cmdlets are .NET classes that are exposed as APIs, commands, and GUIs. Providers are extensions to Windows PowerShell that provide features such as policy verification or metadata augmentation. Help files contain information for different topics, including command descriptions and topics on how to extend Windows PowerShell.

4. Press SPACE BAR until the command prompt returns. Alternatively, you can type the letter Q to cancel the output.

5. To view help information about the **Get-Command** cmdlet, at the Windows PowerShell command prompt, type the following command, and then press ENTER.

        help Get-Command

    The help contains the syntax for the command as well as a brief description.

![Image of Windows PowerShell help output]

Figure 2: Obtaining help for the Get-Command cmdlet

6. To see detailed help for the **Get-Command** cmdlet, at the Windows PowerShell command prompt, type the following command, and then press ENTER.

        help Get-Command -Detailed

    The output includes details about the parameters for the cmdlet, as well as some examples.
7. To view the entire help content for the **Get-Command** cmdlet, at the Windows PowerShell command prompt, type the following command, and then press ENTER.

```
help Get-Command -Full
```

**Figure 3:** Obtaining help for the Get-Command cmdlet in detailed mode

**Figure 4:** View the entire help content for the Get-Command cmdlet
List the commands available in Windows PowerShell

In this step, you will list all available commands in Windows PowerShell.

1. To view the list of available commands, at the Windows PowerShell command prompt, type the following command, and then press ENTER.

```
Get-Command
```

2. Review the list of commands available. Take note of the naming convention for commands with a CommandType of **Cmdlet**.

![Figure 5: List of Windows PowerShell commands](image)

Windows PowerShell uses verb-noun naming conventions to make cmdlets discoverable and obvious in what they do.

3. At the command prompt, type the following command, but do not press ENTER.

```
Get-C
```
4. Press TAB. Windows PowerShell expands the command to `Get-CAAuthorityInformationAccess`.

5. Press TAB again. The command is changed to `Get-CACrlDistributionPoint`.
   - If you do not see these cmdlets, make sure you are performing the steps on DC.

6. You can continue pressing TAB to cycle through all the available commands that begin with `Get-C`. Similarly, you can cycle backwards by pressing SHIFT-TAB.
   - You can easily display a list of available Windows PowerShell commands. In addition, you can enter a portion of a command name and use tab-completion to resolve the partial command to a full Windows PowerShell command.

7. Press ENTER to execute the expanded Windows PowerShell command.

Format and filter output using Windows PowerShell

In this step, you will learn how to use command parameters and cmdlets to filter data. Also, you will learn how to format the displayed output.

1. To view a list of services installed on the computer, at the Windows PowerShell command prompt, type the following command, and then press ENTER.

   ![Get-Service](image)

   - A list of services is displayed.

   ![Figure 6: The Get-Service command](image)
Windows PowerShell provides a complete set of verbs to query and manipulate services, including Get, New, Restart, Resume, Set, Start, Stop, and Suspend. To view a list of service related commands type `Get-Command -Noun Service`.

2. Enter the following to view the status of the Spooler service:

   - `Get-Service -Name Spooler`

   ![Figure 7: Status of the Spooler service](image)

   The Get-Service command resolves the first input as the name parameter when you do not specify a parameter name for the input.

3. Enter the following command to obtain the same result as the previous step.

   - `Get-Service Spooler`

   You can use positioned or named parameters when you invoke cmdlets. Windows PowerShell provides built-in code that relieves cmdlet developers from having to parse program parameters.

4. Type the following command, and then press ENTER to view a list of all services that begin with M.

   - `Get-Service M*`

   The status of all the services beginning with M is shown.

   ![Figure 8: Status of the services beginning with M](image)

   Many cmdlets allow the use of wildcards. You can use the wildcard to filter the results to a subset of all results.

5. Enter the following to see the same list of services. This time, the output is shown in list format.

   - `Get-Service M* | Format-List`
Figure 9: Using the format-list command

In this example, there are two commands separated by a pipe (|) character. This means that the output of the first command is used as the input to the second command.

6. Enter the following to see the same output, this time shown in a custom format.

```powershell
Get-Service M* | Format-Custom
```

The status of all services beginning with M will be shown in the custom format.

Figure 10: Using the Format-Custom command

Windows PowerShell includes several defined format commands, each one with many configuration options. This provides a great deal of flexibility in output formatting. Developers can also create additional format commands.
7. Type the following command, and then press ENTER to view all the running services that begin with M.

```powershell
Get-Service M* | Where-Object {$_.Status -eq "Running"}
```

Only services in a running state are shown this time.

**Figure 11:** Using the Where-Object command to filter the list to show only running services

In this command:

- **Where-Object** is a command for performing a filter on the input.
- `{ }` are delimiters for Windows PowerShell code blocks.
- `$_` refers to the input object (all services that begin with M).
- `-eq` specifies that the left-hand argument, in this case the Status property ($__.Status), will be compared for equality against the right-hand argument, the value “Running”.

8. To view all the stopped services that begin with M, type the following command, and then press ENTER.

```powershell
Get-Service M* | Where {$_.Status -eq "Stopped"}
```

Only those services that are stopped are shown.

**Figure 12:** Using the Where-Object command to filter the list to show only stopped services

This is an example usage of the alias mechanism. Here, Where is an alias for the Where-Object command.

9. To view a list of all services ordered by their status, type the following command, and then press ENTER.

```powershell
Get-Service | Sort-Object Status
```
The Sort-Object command can order objects returned by a previous cmdlet using one or more of their properties. You can also use the alias Sort to refer to the Sort-Object command.

10. Type the following command, and then press ENTER to view the Name and DisplayName of all services beginning with M, with the output ordered and grouped by Status.

```
Get-Service M* | Sort-Object Status | Format-Table -GroupBy Status Name, DisplayName
```

![Image of PowerShell output](image.png)

Figure 13: Using the Sort-Object and Format-Table command to group the output data

View object metadata

Everything in Windows PowerShell is a .NET object, and is available for reflection, including cmdlets, services, and processes. Windows PowerShell extends the .NET type reflector to allow simpler access for administrative purposes.

In this step, you will learn how to view the type members of those objects.

1. To view the type metadata for the object output by the Get-Service command, type the following command, and then press ENTER.

```
Get-Service | Get-Member
```

The type metadata for the object output by Get-Service is displayed. Note that the data type, in this case the System.ServiceProcess.ServiceController class, is also displayed.
Figure 14: Using the Get-Member command to view object metadata

2. To view the type metadata for the object output by the Get-Process command, type the following command, and then press ENTER.

```powershell
Get-Process | Get-Member
```

Figure 15: Members of the System.Diagnostics.Process type

3. To create a new object of type System.Diagnostics.Process and view the type metadata for the class, type the following command, and then press ENTER.

```powershell
```
The type metadata for the System.Diagnostics.Process class is shown.

![Type members of a new object](image)

**Figure 16: Type members of a new object**

4. Type the following command, and then press ENTER to view a list of services that the Spooler service depends on.

   ✈️ Get-Service Spooler | Select-Object ServicesDependedOn

   ✈️ A list of services that the Spooler service requires to start is displayed.

![Inspecting the ServicesDependedOn property of the Spooler service](image)

**Figure 17: Inspecting the ServicesDependedOn property of the Spooler service**

**Using Show-Command**

Metadata information can also be used to identify the inputs needed for a specific command and to retrieve information about the command. Windows PowerShell provides a graphical aid to provide the command input.

In this task, you will learn how to retrieve and provide information needed in a graphical manner by using the Show-Command cmdlet.

1. To view the input metadata for the Get-Service command, type the following command, and then press ENTER.
Show-Command Get-Service

The input metadata fields for the Get-Service command are displayed. This is also an interactive window that allows you to type the necessary fields to retrieve information from local or remote systems.

2. To view the results of Get-Service, in ComputerName, type localhost, and then click Run.
3. Review the results of the execution of Get-Service with the value for the ComputerName parameter set to localhost.

![Figure 18: Get-Service with ComputerName set to localhost](image)

Using whatif and confirm

Windows PowerShell allows administrators to safely test and use commands. In this step, you will use the whatif and confirm commands.

- The [Command] -WhatIf flag shows you the results without actually performing the action.
- The [Command] -Confirm flag asks you to confirm the operation before it executes.

1. Type the following command, and then press ENTER to see a list of services that would be stopped if you ran the Stop-Service command.

   Stop-Service M* -WhatIf

   A list of services that would be stopped is displayed.

   ![Figure 19: The Stop Service command with the Whatif flag specified](image)
2. Type the following command, and then press ENTER to confirm whether or not to stop each service.

```powershell
Stop-Service M* -Confirm
```

- For each service beginning with M, you will be asked if it should be stopped. For this lab, reply No in each case.

![Image of PowerShell console showing the Stop-Service command with the confirm flag specified]

**Figure 20: The Stop-Service command with the confirm flag specified**

### Creating and manipulating variables

In this step, you will work with variables in Windows PowerShell. You will learn about their declaration, usage, and behavior.

1. To create a variable to hold a string value, type the following command, and then press ENTER.

```powershell
$var = "Hi there"
```

- With this command, you created a variable named var, and you assigned the string value Hi there to it.
- A variable in Windows PowerShell must begin with the dollar sign ($). If special characters are needed in a variable name, curly braces can be used to surround the variable name ({}).

2. To output the value stored in this variable, type the following command, and then press ENTER.

```powershell
$var
```

- A better way to output variable values is to use a cmdlet named Write-Host before the variable name, clearly showing it will output the values to the host.

```powershell
Write-Host $var
```

The results should be similar to the following screenshot.

![Image of PowerShell console showing the output of the $var variable]

**Figure 21: Printing a variable value**
By default, a variable will have a null value. Null values in Windows PowerShell are represented as $null.

3. Variables in Windows PowerShell can be listed and accessed under a special location. To display the list of currently declared variables, type the following command, and then press ENTER.

```powershell
Get-Variable
```

![List of currently declared PowerShell variables](image)

Figure 22: List of currently declared PowerShell variables

4. By default, variables in Windows PowerShell are non-typed, which means they can hold an arbitrary value. To change the variable value and type to an integer, type the following command, pressing ENTER after each line.

```powershell
$var = 123
$var
```

Now the variable is holding the integer value 123.

![Assigning an integer value](image)

Figure 23: Assigning an integer value

5. Variables can also contain lists (similar to arrays). To change the value to an array of integers, type the following commands, pressing ENTER after each line.

```powershell
$var = 1,2,3
$var
```

This time, the variable is holding an array of integers.
Figure 24: Creating an array of integers

6. To see the new type of the variable, type the following command, and then press ENTER.

```shell
$var.GetType().FullName
```

- The variable is now an array object of type System.Object[].

Figure 25: Obtaining the type of the variable

Arrays can be also manipulated through their .NET methods. For example, they can be queried on their length.

7. To use the Length property to retrieve the number of elements of the array, type the following command, and then press ENTER.

```shell
$var.Length
```

- The size of the array is displayed.

Figure 26: Displaying the array length

8. You can also access individual elements within an array by using square brackets ([]). To retrieve the second element of the array, type the following command, and then press ENTER.

```shell
$var[1]
```

- Arrays in Windows PowerShell are zero-based, which means that the first element will always be at position (index value) 0.
- The value of the second element of the array is displayed.

Figure 27: Retrieving an element of the array
9. You can also type a variable by prefixing its declaration with the desired data type name. To re-declare the variable as an array of integers, type the following command, and then press ENTER.

```powershell
[int[]] $var = (1,2,3)
```

10. To assign the string value 0123 to the third element of the array, and then display it, type the following commands, pressing ENTER after each one.

```powershell
$var[2] = "0123"
$var[2]
```

![Figure 28: Implicit conversion from string to integer](image)

- Examining the output of the variable, the string 0123 was converted into the number 123. Windows PowerShell implicitly converted the stored value to match the destination variable type.
- Implicit type conversions are done only for typed variables. Unlike strongly typed languages where a variable can only be assigned an object of the correct type, Windows PowerShell allows the assignment of any object, as long as it is convertible to the target type, by the extensive use of implicit conversions.

11. When an implicit conversion is not available, it displays an error. To attempt to set a string value that cannot be converted, type the following command, and then press ENTER.

```powershell
$var[2] = "A string value"
```

![Figure 29: Type conversion error](image)

- The following error is displayed.

---

**Working with strings**

In this step, you will use different operators to deal with strings values in Windows PowerShell.

1. To create and initialize two string variables named var1 and var2, type the following commands, pressing ENTER after each one.

```powershell
$var1 = "Hello 
```
2. To use the plus (+) operator to concatenate the two string variables, type the following command, and then press ENTER.

```
$var1 = "Hello"
$var2 = "world"
$var1 + $var2
```

The result of this operation is a new Hello World string, as shown in the following screen shot.

![Figure 30: Concatenating two string variables](image)

3. You can use the .NET String properties to inspect the string objects. To use the Length property to obtain the size in characters of the previous string concatenation, type the following command, and then press ENTER.

```
($var1 + $var2).Length
```

![Figure 31: Using the Length property](image)

4. Windows PowerShell also provides other kinds of binary operators, like comparison operators. To verify if two strings are equal, type the following command, and then press ENTER,

```
"John Smith" -eq "John Sanders"
```

The result of the comparison is shown in the following screen shot.

![Figure 32: Comparing two strings](image)

There are other comparison operators, like `ne` (not equals) `gt` (greater than), `lt` (less than), `ge` (greater than or equal) and `le` (less than or equals).
For each of these operators there is also a base or unqualified operator form, like `–eq` and its two variants `–ceq` and `–ieq`. The “c” variant is case-sensitive and the “I” variant is case-insensitive.

5. Formatting is a common task that can also be done in Windows PowerShell. To use a custom format to display 12.4 as 12.40, type the following command, and then press ENTER.

```windows
{0:f2} -f 12.4
```

The output should look like the following screenshot.

![Figure 33: Formatting decimal values](image)

6. To display the same number as currency, and then to pad it to 10 characters aligned to the right, type the following command, and then press ENTER.

```windows
"{0,10:C}" -f 12.4
```

The currency symbol configured in the current culture of the local machine is used.

![Figure 34: Formatting currency values](image)

7. Date and time formatting can also be done. To display only hours and minutes from the current date, type the following command, and then press ENTER.

```windows
"{0:hh:mm}" -f (Get-Date)
```

![Figure 35: Formatting date and time values](image)

Creating a script file

Script files are used to store Windows PowerShell commands in a file, providing an easy way to run a list of commands. You only need to tell Windows PowerShell to run the script file.

In this step, you will learn how to create and run script files. To understand the reasons behind the security features of Windows PowerShell, you will be introduced to a Windows PowerShell security feature.
Windows Server 2012 R2 – Windows PowerShell Fundamentals

called execution policies. The execution policy enables you to determine which Windows PowerShell scripts (if any) will be allowed to run on your computer. Windows PowerShell has four different execution policies:

- **Restricted** – No scripts are allowed to run. Windows PowerShell can only be used in interactive mode.
- **AllSigned** – Only scripts signed by a trusted publisher can be run.
- **RemoteSigned** – Downloaded scripts must be signed by a trusted publisher before they can be run.
- **Unrestricted** – No restrictions; all Windows PowerShell scripts can be run.

When you first install Windows PowerShell, the default value for the execution policy will be set to Restricted.

1. To display the current execution policy, type the following command, and then press ENTER.

   ✗ Get-ExecutionPolicy

   ![Figure 36: The current execution policy is displayed](image)

2. Before running a script file, you will have to change the execution policy. To change the execution policy to RemoteSigned and verify the change, type the following commands, pressing ENTER after each one.

   ✗ Set-ExecutionPolicy RemoteSigned
   ✗ Get-ExecutionPolicy

   Changing the execution policy requires administrative privileges. If you are running Windows Vista or Windows 7, on the Start menu, right-click the Windows PowerShell icon, and then click Run as Administrator.

   For other platforms, either log in with an administrative account or open a Windows PowerShell console by using the runas command and supplying appropriate credentials. For example:

   `runas /user:username PowerShell`

   where `username` is an account with administrative privileges.

   Remember that it is best practice to use administrative privileges only for operations that require it.
3. To create the script file, on the taskbar, right-click the Windows PowerShell icon, and then click **Windows PowerShell ISE**.
- To create script files, you don’t need a special editor. In this example you will use the Windows PowerShell Integrated Scripting Environment (ISE). The Windows PowerShell ISE is a host application that enables you to run commands, write, test, and debug scripts in a friendly, syntax-colored, Unicode-compliant environment.

4. On the View menu, click **Show Script Pane**.
- The ISE has two windows, or panes, so you do not need to edit text in a separate application.
  - **The script pane** at the top allows you to compose, edit, debug, and run functions and scripts. Note that the script pane is not displayed by default. To display the script pane, on the View menu, click Script Pane.
  - **The console pane** at the bottom is used for running interactive commands, just as you would in the Windows PowerShell text-based console.

5. In the script pane, type the following commands, pressing ENTER after each line.

   ```powershell
   # test.ps1
   # Show Hello and time.
   
   "" # Blank Line
   "Hello " + $env:UserName + "!
   "Time is " + "{0:HH}:{0:mm}" -f (Get-Date)
   "" # Blank Line
   ```

6. To save the file as a Windows PowerShell script file, on the File menu, click **Save As**.

7. In the file name, type **test.ps1**, in the location, type **C:\users\Administrator\Desktop**, and then click **Save**.
   - When you create your script file, the filename must have a .ps1 extension.

8. Click in the command pane, type the following command, and then press ENTER.

   ```powershell
cd C:\users\Administrator\Desktop
   ```

9. To execute the script file you created in the previous step, type the following command, and then press ENTER.

   ```powershell
   .\test.ps1
   ```
You can follow the same procedure to execute scripts in the Windows PowerShell text-based console. From the ISE, you can also execute a script using the Run command on the File menu.

Preceding the script name with directory information, in this case the current directory (`\`), instructs Windows PowerShell to run a script.

There must be no space between `\` and the script name. Adding the `.ps1` extension is optional. You must specify the path to the script file, even if the script is in the current directory.

![Image](image.png)

**Figure 38: Running the script file from the current directory**

10. To use the `Invoke-Expression` command as an alternative way of running the same script, type the following command, and then press ENTER.

```
Invoke-Expression "C:\Users\Administrator\Desktop\test.ps1"
```
11. To use the invoke operator (&) to execute the command in the string that follows, type the following command, and then press ENTER.

```
& "C:\Users\Administrator\Desktop\test.ps1"
```

12. To close the test.ps1 script, on the test.ps1 tab, click the X.

   ➤ As an alternative, on the File menu, click Close.
Many commands in the ISE have keyboard shortcuts. You can see the keyboard shortcuts to the right of their respective commands in the menus at the top of the ISE. The keyboard shortcut to close the active file in the script pane is Ctrl+F4.

Creating functions

In Windows PowerShell, you can declare functions. Functions are reusable pieces of code that can be called as many times as you want after you declare them.

In this step, you will declare a function, learn about using different types of parameters, and specify default values for these parameters.

1. In the Windows PowerShell ISE, press CTRL+N.
2. In the script pane, type the following code.

```powershell
function Get-Soup {
    [switch] $please,
    [string] $soup = "chicken noodle"
}
{
    if ($please) {
        "Here's your $soup soup"
    }
    else {
        "No soup for you!"
    }
}
```

This command declares a Get-Soup function which will receive two parameters, $please and $soup.

3. To run the script, press F5, and then click the Script arrow to hide the script pane.

   It is not necessary to save a script before executing it in the ISE. This makes it easy to use the script pane to quickly test commands and code snippets.

4. To call the script with no parameters, in the command pane, type the following command, and then press ENTER.

   ```powershell
   Get-Soup
   ```

5. To call the Get Soup function with the $please parameter, type the following command, and then press ENTER.

   ```powershell
   Get-Soup -please
   ```
Since you didn’t specify a value for the $soup parameter, the default value (chicken noodle) is used.

6. To call Get-Soup specifying a value for $soup, type the following command, and then press ENTER.

```powershell
Get-Soup –please tomato
```

Working with providers

Windows PowerShell providers enable you to access data that would not otherwise be easily accessible at the command line. The data that a provider exposes appears in a drive, much like a hard drive, and is presented in a consistent format that resembles the file system. You can use any of the built-in cmdlets that the provider supports to manage the data in the provider drive, in addition to custom cmdlets that are designed especially for the data. By default, Windows PowerShell includes several providers that allow you to access common data stores in Windows, such as the file system, registry, and certificate store.

In this step, you will list the available providers and the drives which make use of these providers. You will also create a new drive using the registry provider.

1. On the taskbar, click **Windows PowerShell**.

2. To display a list of the available providers, type the following command, and then press ENTER.

```powershell
Get-PSProvider
```

![Figure 41: List of Windows PowerShell providers](image1.png)

3. To display a list of the available drives, type the following command, and then press ENTER.

```powershell
Get-PSDrive
```

![Figure 42: List of Windows PowerShell drives](image2.png)
4. To create a new drive for the HKEY_CLASSES_ROOT hive in the registry using the Registry provider, type the following command, and then press ENTER.

```
New-PSDrive -Name HKCS -PSProvider Registry -Root "HKEY_CLASSES_ROOT"
```

![Figure 43: Adding a new Windows PowerShell drive](image)

- As with the file system, the registry can also be modified using Windows PowerShell drives. Be aware that when modifying the registry, changes may cause the system to fail.

5. To browse to the newly created drive, called HKCS, as if you were working with a drive in the file system, type the following commands, pressing ENTER after each one.

```
.cd HKCS:
.dird .ht*
```

- This will set the current location to the newly created HKCS drive, and then display the list of registry entries that match the filter expression.

- **IMPORTANT:** The trailing colon (:) after the drive name indicates a drive change which is different from a folder change. The colon is necessary; otherwise, Windows PowerShell will display an error.

![Figure 44: Browsing the HKCS drive](image)

6. To change the current folder to another folder inside the HKCS drive, and then list its contents, type the following commands, pressing ENTER after each line.

```
.cd .html
.dird
```

![Figure 44: Browsing the HKCS drive](image)
Many of the same commands used to manipulate the file system, such as cd and dir, also work with other providers.
Exercise 2: Working with Windows PowerShell ISE

You can use the Windows PowerShell Integrated Scripting Environment (ISE) to create, run, and debug commands and scripts. The Windows PowerShell ISE consists of the menu bar, Windows PowerShell tabs, the toolbar, script tabs, a script pane, a console pane, a status bar, a text-size slider and context-sensitive Help. It works for both local and remote scripts.

Using the Windows PowerShell ISE gives you many different advantages when creating scripts. Although it can be used for interactive commands, the best use of the tool is for script creation and debugging.

Getting to know Windows PowerShell ISE

In this step, you will explore the layout of Windows PowerShell ISE.

1. To open a new Windows PowerShell ISE environment window, on the taskbar, right-click Windows PowerShell, and then click Run ISE as Administrator.

![Windows PowerShell ISE](image)

Figure 46: Windows PowerShell ISE

2. On the View menu, click Show Script Pane.
   - The command pane to the right shows a list of commands based on the modules that are currently loaded.
In this step, you will learn how to use IntelliSense in the Windows PowerShell ISE script pane.

1. In the script pane, type `Get-`. 
2. As you type, you will see a list of possible commands. Continue typing `Get-Ser`.  
   ✤ Get-Service will be selected and the possible complete syntax will be displayed.
3. Press TAB.
4. Press SPACE BAR.
5. Type `-`.  
   ✤ A list of possible parameters will appear.
6. Continue typing `Computer`, press TAB, and then press SPACE BAR.
7. Type `DC`.  
8. Press F5 to execute the command.
The command pane in Windows PowerShell ISE

In this step, you will use the command pane in Windows PowerShell ISE.

1. In the command pane, in the Name box, type `Get-Service`. ✤ As you type, the commands will be filtered.
2. In the filtered results, click the `Get-Service` command. ✤ The parameters for the command will appear. Review the Default, DisplayName, and InputObject tabs.
3. In the ComputerName parameter, type `DC`, and then press F5 to run the command. ✤ Review the results of all available services on the target system.
4. In the Name parameter, type `TermService`, and then press F5 to run the command.
5. In the command pane, select the `Insert` option. ✤ The command will be inserted into the interactive Windows PowerShell console pane.
7. Review the parameters list.

Snippets in Windows PowerShell ISE

The script pane in Windows PowerShell ISE has predefined blocks of code that assist you in creating your scripts. Those blocks are called snippets. In this step, you will use snippets in the Windows PowerShell ISE.

1. In the script pane, delete any existing lines.
2. In the script pane, type the following command, and then press ENTER.
   $$process = Get-WmiObject -Class win32_process

3. To access the snippets, press Ctrl+J, type `foreach`, and then press TAB. ✤ The following block will be displayed:
   ```powershell
   foreach ($item in $collection)
   {
   }
   ```

4. Replace `$collection` with `$process`.
5. Inside the script block, in between the curly braces, type the following command:
   ```powershell
   $item.name
   ```

6. The complete script block will be:
   ```powershell
   foreach ($item in $process)
   {
   ```
6.7. Press F5 to execute the script.

 despair  A list with the running processes in the system will be returned.

This is the end of the lab
